

Lightning Network: Reliability and Structural-Concentration Synthesis (Fig. 4)

*Panels 1-2 are NOT like-for-like measurements of the same quantity: panel 1 is decentralized mesh-wide reachability, panel 2 is one large custodial node's own platform success rate. Panel 3 is structurally different evidence again -- an inequality metric on the public channel graph, computed independently by separate research teams using separate methodologies (Lin, Primicerio, Squartini, Decker & Tessone, 2020, New J. Phys.; Zabka, Foerster, Decker & Schmid, 2022, FC; Atmanaviciute, Vanagas & Masteika, 2025, IEEE Access; exact point estimates differ slightly by study and methodology, so values shown here are representative anchors within each study's reported range, not a single author's precise series) -- and it moves in the same direction as panels 1-2 continuously across seven years, not at one measurement date. This convergence across independent methods is the strongest evidence in this paper for the hub-formation prediction of Fig. 3, considerably stronger than panels 1-2 alone.*
